

# HTML Newspaper Recreation - Code Explanation

This document explains the structure and layout approach used to recreate a printed newspaper front page in English using HTML5, semantic tags, inline styles, and table-based columns.

## 1. Code Structure

The file follows a clear top-to-bottom structure: semantic layout containers first, then content blocks grouped into sections, with each story placed inside an article.

- **<head>** includes metadata and the document title.
- **<body>** contains the full front page in a single flow.
- Inline **style** attributes control spacing, borders, colors, and alignment.

## 2. Key Sections

- **Header (masthead):** newspaper name/title and masthead image; thick rules simulate print styling.
- **Nav:** a simple link list for major areas; implemented with an unordered list.
- **Main content:** grouped into three major sections (top stories, middle grid, lower grid).
- **Footer:** brief submission notes; closes the page with a strong rule like a print footer.

## 3. Design Decisions

Tables were used to create predictable newspaper columns and satisfy the rubric requirement for at least one table-based layout. Semantic tags (header, nav, section, article, footer) improve readability and match HTML5 best practices. Colored headline strips were recreated using inline background colors and borders to mimic the original visual hierarchy.

- **Tables vs divs:** fixed column widths keep story blocks aligned like print columns.
- **Heading hierarchy:** H1 for the newspaper title; H2/H3 for major stories; H4 for subheads.
- **Accessibility:** all images include alt text; links use readable labels.

## 4. Challenges

The main difficulty was approximating a dense print layout using only HTML and inline styles while keeping the document clean and valid HTML5. Maintaining consistent spacing, borders, and readable typography across multiple stories required careful tuning of table cell padding and font sizes.
